BGP Videos

- NSRC has made a video recording of this presentation, as part of a library of BGP videos for the whole community to use:
 - https://learn.nsrc.org/bgp#ixp_design

The screenshot shows the NSRC (Network Startup Resource Center) website. The navigation bar includes links for Home, About, BGP for All (highlighted), perfSONAR, ScienceDMZ, FedIdM, and Contact Us, along with a search bar. The main content area is divided into three columns:

- BGP for All:** A text-based introduction to BGP, explaining it as the primary routing protocol for the Internet and autonomous systems. It also mentions that understanding routing options can lead to efficiencies for institutions and research/education networks.
- Introduction to Routing:** A list of video topics including Internet Routing, Routing Protocols, Introduction to IS-IS (UPDATED), IS-IS Levels, IS-IS Adjacencies, Best Configuration Practices for IS-IS on Cisco IOS, IS-IS Authentication, Default Routes and IPv6, Introduction to OSPF, OSPF Areas, OSPF Adjacencies, Best Configuration Practices for OSPF on Cisco IOS, OSPF Authentication, Default Routes and IPv6, Comparing OSPF and IS-IS, Choosing between OSPF and IS-IS, Migrating from OSPF to IS-IS, Migration Plan, and Finalizing Migration.
- Introduction to BGP:** A list of video topics including Introduction to Border Gateway Protocol, Transit and Peering, Autonomous Systems (UPDATED), How BGP works, Supporting Multiple Protocols, IBGP versus EBGP, Setting up EBGP, and Setting up IBGP.

On the right side, there is a video player for "BGP for All" with a play button and a "Watch on YouTube" button. Below the video player, there are sections for "BGP Case Studies" (listing Peering Priorities, Transit Provider Peering at an IXP, Customer Multihomed between two IXPs, Traffic Engineering for an ISP connected to two IXes, Traffic Engineering for an ISP with two interfaces on one IX LAN, and Traffic Engineering and CDNs) and "Communities" (listing RFC 1998 Traffic Engineering, Simplifying Traffic Engineering, and How to Apply Communities to Originated Routes).

IXP Design

- Background
- Why set up an IXP?
- Layer 2 Exchange Point
- Design Considerations
- Route Collectors & Servers
- What can go wrong?

A bit of history

Where did the IXP concept come from?

A Bit of History...

- NSFnet – one major backbone
 - US “National Science Foundation” funded
 - Connected academic & research institutions
 - Also connected “private company” networks, under acceptable use policy (AUP), at network access points
 - **AUP: No commercial activity**
- Four Network Access Points (NAPs)
 - Chicago (IL) – run by Ameritech
 - New York (NY) – run by Sprint
 - San Francisco (CA) – run by PacBell
 - Vienna (VA) – run by MFS

More History...

- Private companies needed to interconnect their networks too
 - Requirement to send “commercial traffic”
 - Could not cross NSFnet due to AUP
- Resulted in the first “commercial Internet Exchanges” in the early 1990s:
 - CIX-West – west coast USA (Bay Area)
 - MAE-East – east coast USA (Virginia)
- Routing Arbiter project helped with coordination of routing exchange between providers
 - Traffic from ISP A needs to get to ISP B
 - Now superseded by today’s Internet Routing Registries (IRR)
 - The RADB is the remnant of the Routing Arbiter project

More History still...

- End of the NSFnet in 1995:
 - Meant move towards commercial Internet
 - Private companies selling their bandwidth
- The NAPs established late in NSFnet life were some of the original “exchange points”
 - NAP operators were providing commercial Internet access as well
 - Sprint, PacBell and Ameritech NAPs were replaced by neutral/commercial IXPs
 - The MFS hosted MAE-East replaced the Vienna NAP
 - ANS (operator of the late NSFnet) forced to join IXPs
- A global Distributed GIX proposed in mid 1990s
 - But never happened (planned to be CIX-West, MAE-East, SE-GIX and a Paris IX)

Even more History

- SE-GIX formed in Stockholm in 1992
 - Three major ISPs interconnected
 - Latency reduction, performance gains
 - Local traffic stays local
 - (Proposed to be part of the D-GIX)
- LINX formed in London in 1994
 - Five UK operators interconnected
 - Latency reduction, performance gains
 - Local traffic stays local
 - (Proposed to be part the D-GIX when Paris fell through)
- HKIX formed in Hong Kong in 1995
 - Vibrant Internet community, many small operators
 - Latency, performance, and local traffic benefits

Internet Exchange Point

- What:
 - **An open & neutral location where network operators freely interconnect their networks to exchange traffic**
- What is the physical IXP?
 - An ethernet switch in a neutral location
- How does it work:
 - IXP Host provides the switch and rack space
 - Network Operators interconnect via the IXP fabric
 - Either bring their own router and install at the IXP
 - Or run fibre/wireless link (point to point ethernet) from their location to IXP
- Very simple concept – any place where providers meet to exchange traffic

Internet Exchange Point

- Layer 2 exchange point
 - Ethernet (400Gbps/100Gbps/10Gbps/1Gbps)
 - Older technologies used in the past included ATM, Frame Relay, SRP, FDDI and SMDS
- Layer 3 exchange point
 - *Has had historical status since mid-90s*
 - Router based
 - Best known example was CIX-West
 - Router quickly overwhelmed by the sophisticated requirements of the rapidly growing Internet

Why an Internet Exchange Point?

Saving money, improving QoS,
Generating a local Internet economy

Internet Exchange Point

Why peer?

- Consider a region with one ISP
 - They provide internet connectivity to their customers
 - They have one or two international connections
- Internet grows, another ISP sets up in competition
 - They provide internet connectivity to their customers
 - They have one or two international connections
- How does traffic from customer of one ISP get to customer of the other ISP?
 - Via the international connections

Internet Exchange Point

Why peer?

- Yes, International Connections...
 - Major content may be tens if not hundreds of milliseconds away
 - If geostationary satellite, RTT is around 550ms per hop
 - So local traffic between two operators would take over 1s round trip
 - Huge disincentive for a local Internet economy

- International bandwidth
 - Costs significantly more than domestic bandwidth
 - Is congested with local traffic
 - Local traffic on international links wastes money for both operators, harms overall performance for all users

Internet Exchange Point

Why peer?

□ Solution:

- Two competing ISPs peer with each other

□ Result:

- Both save money
- Local traffic stays local
- Better network performance, better QoS,...
- More international bandwidth for expensive international traffic
- Everyone is happy

Internet Exchange Point

Why peer?

- A third ISP enters the equation
 - Becomes a significant player in the region
 - Local and international traffic goes over their international connections

- All three ISPs agree to peer with each other to:
 - Save money for all three
 - Keep local traffic local
 - Improve network performance
 - Improve service quality for end users
 - Improve value proposition for local content hosting

Internet Exchange Point

Why peer?

- Private peering means that the three ISPs have to buy circuits between each other
 - Works for three ISPs, but adding a fourth or a fifth means this does not scale
- Solution:
 - Internet Exchange Point

Internet Exchange Point

- Every participant has to deploy just one link
 - From their premises to the IXP
- Rather than $N-1$ links to connect to the $N-1$ other ISPs
 - 5 ISPs will have to share the cost of 4 links = 2 whole links → already twice the cost of the IXP connection

Internet Exchange Point

□ Solution

- Every ISP participates in the IXP
- Cost is minimal – one local link covers all domestic traffic
- International links are used for just international traffic – and backing up domestic links in case the IXP suffers any outage

□ Result:

- Local traffic stays local
- QoS considerations for local traffic is not an issue
- RTTs between members are typically sub 1ms
- Customers enjoy the Internet experience
- Local Internet economy grows rapidly

Who can join an IXP?

- Requirements are very simple: any organisation which operates their own autonomous network, and has:
 - Their own address space
 - Their own AS number
 - Their own transit arrangements
- This often includes:
 - Commercial ISPs
 - Academic & Research networks
 - Internet infrastructure operators (eg Root/ccTLDs)
 - Content Providers & Content Distribution Services
 - Cloud and Hosting Providers
 - Broadcasters and media
 - Government Information networks

When an IXP is not beneficial

- **Legislation**: When there is one legislated monopoly transit provider
 - With all other network operators are legislated to be customers of this monopoly provider

- **Geography**: When the local economy is so small that it cannot sustain more than one network operator
 - Very small nations (maybe less than 10000 population?)
 - Sparsely populated / remote areas

When an IXP is not permitted

- This is still the situation in several countries around the world
- Usually it is a Government operated “national telco”
 - ISP licence **mandates** connecting to “national telco” for Internet services
- Implications:
 - **Expensive** domestic connectivity
 - **Expensive** international connectivity
 - **Restricted** and **poor** service offerings
 - No domestic Internet economy
 - Everyone loses, especially the “national telco”

Layer 2 Exchange

The global industry standard IXP

IXP Design

- Very simple concept:
 - Ethernet switch is the interconnection media
 - IXP is one LAN
 - Each member brings a router, connects it to the ethernet switch provided at the IXP
 - Alternatively, the member runs fibre/wireless from their datacentre to the IXP location, and connects to the IXP switch (point-to-point ethernet)
 - Each ISP peers with other participants at the IXP using BGP
- Scaling this simple concept is the challenge for the larger IXPs

IXP Design – Layer 2

Single site internet exchange point

IXP Design – Layer 2

Dual site internet exchange point – not interconnected

Layer 2 Exchange

- Two switches for redundancy
 - Separate sites is best
 - Do not interconnect the switches
 - Reduces failure modes and complexity
- ISPs use dual routers for redundancy or loadsharing
- Hosts services for the “common good”
 - IXP Website
 - IXP info, membership list, membership portal, how to join, etc
 - Content Distribution Networks
 - DNS Root & TLDs
 - NTP servers
 - Routing Registry and Looking Glass

Layer 2 Exchange: Location

- Neutral
 - Anyone can install fibre or other connectivity media to access the IXP
 - Without cost or regulations imposed by location
- Secure
 - Best practice physical and logical security, like any other network data centre
- Accessible
 - Easy/convenient for all participants to access
- Safe
 - Low risk from natural disaster (cyclone, earthquake, tsunami, wildfire)
- Expandable
 - IXPs cause local Internet economy growth, and therefore increasing space requirements within the facility

Layer 2 Exchange: Location

□ Good:

- Carrier Neutral Data Centre (ideal!)
- Technology Park
- University
- Large Enterprise
- Check: All need 24x7 power/access/security

□ Bad:

- ISP Data Centre (not neutral / ISP perceived advantage)
- Government Data Centre (highly sensitive / security risk)
- Cable Landing Station (national security / physical access / not neutral / tsunami risk)

□ Realistically:

- Compromise sometimes needed!

Layer 2 Exchange: Operations

- Operation:
 - Requires neutral IXP management
 - “Consortium”
 - Representing all participants
 - “Management Board” etc
- Funding:
 - All costs agreed and covered equally by IXP participants
 - Hosting location often contributes – the IXP brings them more business
- Availability:
 - 24x7 cover provided by hosting location
 - Managed by the consortium

Layer 2 Exchange: Technical

□ Configuration

- Recommendation: Public address space for IXP LAN
 - IPv4 (/24) and IPv6 (/64)
 - Most Regional Internet Registries have specific policies so that IXPs can get address space for the IXP LAN and the management infrastructure
- ISPs each require an ASN, basic IXP does not

□ Network Security Considerations

- LAN switch needs to be securely configured
- IXP Management & Services router(s) require well protected access
- IXP services must be behind router(s) with strong filters

IXP Standards

- Industry Standards documented by Euro-IX, the European IXP Association
 - Contributed to by the Euro-IX members
 - <https://www.euro-ix.net/en/forixps/set-ixp/>
- IXP BCP
 - General overview of the infrastructure, operations, policies and management of the IXP
 - <https://www.euro-ix.net/en/forixps/set-ixp/ixp-bcops/>
- IXP Website BCP
 - <https://www.euro-ix.net/en/forixps/set-ixp/ixp-bcops/ixp-website/>

“Layer 3 Exchange”

Why this is not an IXP

“Layer 3 IXP”

- Layer 3 IXP today is marketing concept used by Transit ISPs
 - Some incumbent telcom operators call their domestic or international transit businesses “Exchanges”
- Real Internet Exchange Points are only Layer 2
 - L2 is the accepted International standard

“Layer 3 IXP” – what breaks

- One extra AS hop between peers
 - Makes path via IXP suboptimal/less preferred
 - Path between peers usually remains with upstream transit provider
 - Unless both peers actively implement BGP policies to prefer the L3 IXP
- Members cannot peer with whom they please
 - Mandatory multilateral peering
 - Third party (L3 IXP operator) required to configure peering sessions and peering policy

“Layer 3 IXP” – what breaks

- More complicated troubleshooting
 - Troubleshooting peering problems has to involve IXP operator too
- No policy control
 - BGP attributes shared between members get dropped by IXP router
 - (Examples are BGP communities, MEDs)

“Layer 3 IXP” – what breaks

- CDNs won't join
 - They have requirements to peer directly with IXP members
- Redundancy problems
 - L3 IXPs with dual sites appear as two separate transit providers between peers
 - Traffic engineering?
- L3 IXP Operator requires strong BGP skills

IXP Design Considerations

Exchange Point Design

- The IXP Core is an Ethernet switch
 - It must be a managed switch
 - It must have reasonable security features
 - <https://www.euro-ix.net/ixp-wishlist> has more details
- Has superseded all other types of network devices for an IXP
 - From the cheapest and smallest managed 12 or 24 port 1G/10G switch
 - To the largest switches now handling high densities of 10GE, 100GE and 400GE interfaces

Exchange Point Design

- The basic switch installed at new IXPs today:
 - 48 fibre ports in 1RU (rack unit) with dual redundant power supplies
 - Each port supports 1G or 10G fibre connections via SFP
 - Some also support the new 25G standard on the same port
 - Members can upgrade their link by swapping SFP
 - Most have 40G or 100G “uplink” ports
 - Can be used for connecting high volume CDNs, *or*
 - Expanding the IXP to provide 96-ports in one location
 - Full SNMP, SSHv2, port security, etc
- A few current examples:
 - Juniper: QFX5120-48Y & EX4650-48Y
 - Cisco: Nexus C36180YC-R & Catalyst C9500-48Y4C
 - Arista: 7050SX3-48YC8 & 7060SX2-48YC6

Exchange Point Design

- Each member participating at the IXP brings a router to the IXP location
 - Note that with increased availability of fibre access, members connect directly to the IXP without provisioning a dedicated router at the IXP location
- Router needs:
 - One Ethernet port to connect to IXP switch
 - One WAN port to connect to the WAN media leading back to the ISP backbone
 - To be able to run BGP

Exchange Point Design

- IXP switch located in one equipment rack dedicated to IXP
 - Also includes other IXP operational equipment
- Participants' routers are located in neighbouring rack(s)
- Copper (UTP) connections used for 1Gbps connections
- Fibre used for 1Gbps, 10Gbps, 25Gbps*, 40Gbps**, 100Gbps and 400Gbps connections
 - Fibre is more scalable, allowing IXP member to start with 1Gbps and upgrade to bigger bandwidths simply by swapping the SFP

* 25Gbps is available on newer switches (SFP28 has same form factor and is backwards compatible with SFP+)

** 40Gbps is being phased out in favour of 100Gbps (QSFP28 has same form factor as QSFP+)

Peering

- Each participant needs to run BGP
 - They need their own AS number
 - **Public** ASN, **NOT** private ASN
- Each participant configures external BGP directly with the other participants in the IXP
 - Peering with all participants
 - or*
 - Peering with a subset of participants

Types of Peering at an IXP

- *Bi-lateral Peering*
 - Very similar to Private Peering, but usually takes place at a public peering point (IXP)
- *Multilateral Peering*
 - Takes place at Internet Exchange Points, where operators all peer with each other via a Route Server
- *Mandatory Multilateral Peering*
 - Where operators are forced to peer with each other as condition of IXP membership
 - **Strongly discouraged: Has no record of success**
 - (But some are still determined to prove 30 years of industry experience wrong 😬)

Types of Operator Peering Policies

□ *Open Peering*

- Where a network operator publicly states that they will peer with all parties who approach them for peering
- Commonly found at IXPs where the member participates via the Route Server

□ *Selective Peering*

- Where a network operator's peering policy depends on the nature of the operator who requests peering with them
- At IXPs, the operator will not peer with the Route Server but will only peer bilaterally

□ *Restrictive Peering*

- Where a network operator decides who its peering partners are, and is generally not approachable to considering peering opportunities

Operators Peering Activities

- The Peering Database documents ISPs peering policies and contact information
 - <https://peeringdb.com>
- All operators of ASNs are encouraged to register in the peeringdb
 - All operators who are considering peering or are peering must be in the peeringdb to enhance their peering opportunities
- Participation in peering fora is encouraged too
 - Global Peering Forum (GPF)
 - Regional Peering Fora (European, Middle Eastern, African, Asian, Caribbean, Latin American)
 - Many countries now have their own Peering Fora

Routing Advice

- Member border routers at the IXP must NOT be configured with a default route or carry the full Internet routing table
 - Carrying default or full table means that this router and the member network is open to abuse by non-peering IXP members
 - Correct configuration is only to carry routes offered to IXP peers on the IXP peering router

- Note: Some network operators offer transit across IX fabrics
 - They do so at their own risk – see above
 - (It's not the IXP's concern what the member offers by way of services as long as what they do does not impact the IXP's operation)

Routing Advice (more)

- Member border routers at the IXP must not be configured to carry the IXP LAN network within their iBGP
 - Use next-hop-self BGP concept (refer to BGP Introduction and BGP Attributes presentations)
 - Carrying the IXP LAN address block in the IGP (OSPF or IS-IS) ensures that traceroutes do not break

- Member should not generate their aggregates on IXP peering router
 - If connection from backbone to IXP router goes down, normal BGP failover will then be successful

Address Space

- Some IXPs use private addresses for the IXP LAN
 - Their claim is that public address space means IXP network could be leaked to Internet which may be undesirable
 - But most network operators filter RFC1918 address space, so this avoids the problem
- Most IXPs use public addresses for the IXP LAN
 - Address space available from the RIRs via specific RIR policies
 - IXP terms of participation often forbid the IXP LAN to be carried in the member BGP
- IXPs provide both IPv6 and IPv4 support on the IXP LANs
 - No need for separate LANs for IPv6 and IPv4

Autonomous System Numbers

- IXPs by themselves do not require ASNs
 - Ethernet switch is L2 device, and does not run BGP
- Some IXPs have a Route Collector
 - This usually runs in a private ASN
- Some IXPs have a Route Server
 - This can use either a private or public ASN
- Some IXPs have “common good services”
 - These usually require Internet transit
 - Meaning the IXP services infrastructure requires a transit router
 - IXP arranges transit for services with a couple of providers
 - And this transit router requires a Public ASN and Public Address space
 - This ASN/address space is **separate** from what is used by the IXP fabric itself

Hardware

- Ethernet switch needs to be managed
 - This means CLI access as well as SNMP (at least SNMPv2)
 - CLI allows direct troubleshooting of configuration and operational problems
 - Unmanaged switches mean an unmanageable IXP
- Insist that IXP participants connect a router (L3) port to the IXP switch
 - Avoid spanning tree and L2 security issues
 - Run port security or MAC filtering to protect the IX
- Insist that IXP participants bring their own router
 - Moves buffering problem off the IXP switch
 - (Fibre access to IX reduces this requirement)
 - Security of the member connection is responsibility of the member, not the IXP

Charging

- IXPs need to be run at minimal cost to its member participants
- Common examples:
 - Datacentre hosts the IXP for free
 - IXP members pay a flat annual fee (cost recovery)
 - Differential pricing per port (line card basis)
- IXPs do **NOT** charge for traffic crossing the switch fabric
 - They are a peering enabler, encouraging as much traffic as possible between members

Charging:

Datacentre hosts IXP for free

- Datacentre covers all costs relating to the IXP
 - They provide the switch and supporting infrastructure
 - They provide the operator cover
 - They benefit from the business the IXP members and their customers bring to the DC
 - They benefit from the “prestige” of hosting the IXP and its ancillary services
- The IXP does not charge members for anything at all
 - Example: Seattle IX

Charging:

IXP Members pay flat fee

- Each member pays a flat annual fee towards their IXP membership
- How it works:
 - Cost of switch and ports
 - Cost of operator support
 - Datacentre cost: power, air-conditioning, etc
 - Cost of IXP membership association
 - Contingency needed for new equipment and upgrades
- Total annual cost shared equally amongst members
 - The more members, potentially the lower the costs for each

Charging:

Differential pricing by port

- IXP Member pays according to the port speed they require (big IXP switches)
 - One linecard may handle:
 - 4 100GE ports; or
 - 24 10GE/25GE ports; or
 - 96 1GE ports
 - A 96-port 1GE card is tenth of the price of a 24-port 10GE card
 - Relative port cost is passed on to participants
 - Plus share in the cost of the switch
 - Plus all the costs mentioned in the flat-fee model
- IX members pay according to the cost of provisioning their port speed
 - Example: Netnod IXPs in Sweden

Notes about charging

- Smaller or new IXPs:
 - Free, or flat fee, for members
 - 1RU switch supporting 1G/10G on all ports
 - Members are responsible for providing suitable optics

- Larger or longer established IXPs:
 - Chassis based switches, linecards have different costs
 - Members pay contribution to cost of linecard (hence port charge), often including cost of optics too

Services Offered

- Services offered should not compete with members (basic IXP)
 - e.g. web hosting by the IXP is a bad idea unless all members agree to it
- IXP operations need to make performance and throughput statistics available to members
 - Use tools such as LibreNMS to produce IXP throughput graphs for member (or public) information

Services to Offer

- DNS Root server
 - Anycast instances of F, I and L root nameservers are present at many IXPs
- ccTLD DNS
 - The country IXP could host the country's top level DNS
 - e.g. "SE." TLD is hosted at Netnod IXPs in Sweden
 - Offer back up of other country ccTLD DNS
- gTLD DNS
 - .com & .net are provided by Verisign at many IXPs

Services to Offer

- Route Server
 - Helps scale IXPs by providing easier BGP configuration & operation for participants with Open Peering policies
 - Technical detail covered later on
- Looking Glass
 - One way of making the Route Server routes available for global view (e.g. www.traceroute.org)
 - Public or members-only access
- RPKI Validator Cache
 - Provides RPKI info so that RPKI-based Route Origin Validation can be implemented on the Route Server
 - Also make cache available for member use ?

Services to Offer

- Content Redistribution/Caching
 - Various providers offering content distribution services
 - Broadcast media
- Network Time Protocol
 - Locate a stratum 1 time source (GPS receiver, atomic clock, etc) at IXP
- Routing Registry
 - Used to register the routing policy of the IXP membership (more later)

Notes on IXP Services

- If IXP is offering services to members:
 - Services need transit access
 - Transit needs to be arranged with one or two IXP members (cost shared amongst all members)

- Consider carefully:
 - Should services be located at the IXP itself?
 - How to arrange and pay for the transit to those services?
 - or-
 - Should services be hosted by members and shared with the others?

Introduction to Route Collectors

What routes are available at the IXP?

What is a Route Collector?

- ❑ Usually a router or Linux system running BGP software
- ❑ Gathers routing information from member routers at the IXP
 - Peers with each member using BGP
- ❑ Does **not** forward packets
- ❑ Does **not** announce any prefixes to members

Purpose of a Route Collector

- To provide a public view of the Routing Information available at the IXP
 - Known more commonly as a **Looking Glass**
 - Useful for existing members to check functionality of BGP filters
 - Useful for prospective members to check value of joining the IXP
 - Useful for the Internet Operations community for troubleshooting purposes
 - E.g. **www.traceroute.org**

Route Collector at an IXP

Route Collector Requirements

- Router or Linux system running BGP
 - Minimal memory requirements – only holds IXP routes
 - No packet forwarding requirements – doesn't forward any packets
- Peers eBGP with every IXP member
 - Accepts everything; Gives nothing
 - Uses a private ASN
 - Connects to IXP Transit LAN
- “Back end” connection
 - Second Ethernet globally routed
 - Connection to IXP Website for public access

Route Collector Implementation

- Most IXPs now implement some form of Route Collector
 - Usually as a Route Server (see next section)
- Benefits already mentioned
- Great public relations tool
- Unsophisticated requirements
 - Just runs BGP

Looking Glass

- Looking Glass is a web front end giving limited access to a router or route-collector/server for:
 - Viewing the BGP table
 - Viewing individual paths
 - Checking traceroute and ping to destinations
 - Checking RPKI status
- Implementations include:
 - Birdspy: <https://github.com/nixcz/birdspy/> (only for bird)
 - G Mazoyer's Looking Glass: <https://github.com/gmazoyer/looking-glass>
 - John Frazier's original: <http://mrlg.op-sec.us/>
 - John Heasley's built in to RANCID: <https://shrubbery.net/rancid/>

Introduction to Route Servers

How to scale IXPs

What is a Route Server?

- Has all the features of a Route Collector
- But also:
 - Announces routes to participating IXP members according to their routing policy definitions
- Implemented using the same specification as for a Route Collector

Features of a Route Server

- Helps scale route distribution for IXPs
 - Forwarding of packets is unaffected
 - Makes use of BGP functionality known as “third party next-hop”
- Simplifies Routing Processes on ISP Routers
- Optional participation
 - Provided as service, is **NOT** mandatory
- If traditional router used, will result in insertion of RS Autonomous System Number in the AS Path
 - To be avoided
- Optionally could use Policy registered in the Internet Routing Registry

Diagram of N-squared Peering Mesh

- For large IXPs (dozens of participants) maintaining a larger peering mesh becomes cumbersome and often too hard

Peering Mesh with Route Servers

- ISP routers peer with the Route Servers
 - Only need to have two eBGP sessions rather than N

Route Server based Exchange Point Routing Flow

TRAFFIC FLOW
ROUTING INFORMATION FLOW

Using a Route Server: Advantages

- Advantageous for large IXPs
 - Helps scale eBGP mesh
 - Helps scale prefix distribution
 - Helps implement Route Origin Validation
 - Helps implement bogon prefix and AS filtering

- Separation of Routing and Forwarding

- Simplifies BGP Configuration Management on ISP routers
 - Don't need to maintain a large number of eBGP peers
 - eBGP peering only with the Route Server

Using a Route Server: Disadvantages

- ISPs can lose direct policy control
 - If RS is the only peer, ISPs have no control over who their prefixes are distributed to
 - Standard set up for ISPs with Open Peering Policy

- Completely dependent on 3rd party
 - Configuration, troubleshooting, reliability, etc...

- Possible insertion of RS ASN into routing path
 - (If using a router rather than a dedicated route-server BGP implementation)
 - Traffic engineering/multihoming needs more care

Typical usage of a Route Server

- Route Servers are provided as an **OPTIONAL** service
 - Most IXPs now offer a Route Server as a service to members

- ISPs peer:
 - Directly with significant peers
-and-
 - With Route Server for the rest

- ISPs with an Open Peering Policy usually prefer to peer with a Route Server

Route Server implementations

- Linux/FreeBSD server:
 - BIRD – the standard & works best
 - <http://bird.network.cz>
 - GoBGP
 - <https://osrg.github.io/gobgp/>
 - OpenBGPd:
 - <https://www.openbgpd.org/>
 - FRR (fork of Quagga)
 - <https://www.frrouting.org/>
 - Quagga (LINX fork)
 - <https://github.com/bbonev/quagga.euro-ix/>

Route Server implementations

□ Router:

- Any router (but has RS AS in the AS-path)
- Cisco IOS 15.2 and IOS XE 3.7 onwards has route-server-client support:

```
neighbor 172.16.1.1 route-server-client
```

- Juniper as of JunOS 17.4 has route-server-client support:

```
set routing-instances protocols bgp group <name> route-server-client
```

- It is generally not recommended to use a router as a Route Server
 - Even with the route-server-client support now included

Things to think about...

- Would using a route server benefit you?
 - Helpful when BGP knowledge is limited (but is NOT an excuse not to learn BGP)
 - Avoids having to maintain a large number of eBGP peers

What can go wrong...

The different ways IXP operators harm
their IXP...

What can go wrong?

Concept

- ❑ Some Service Providers attempt to cash in on the reputation of IXPs
- ❑ Market their Internet transit services as “Internet Exchange Point”
 - “We are exchanging packets with other ISPs, so we are an Internet Exchange!”
 - So-called Layer-3 Exchanges – they really are Internet Transit Providers
 - Router(s) used rather than a Switch
 - Most famous example: SingTelIX

What can go wrong?

Financial

- ❑ Some IXPs price their IXP out of the means of most providers
 - An IXP is intended to encourage local peering
 - Acceptable charging model is minimally cost-recovery only
- ❑ Some IXPs charge for port traffic
 - IXPs are not a transit service, charging for traffic puts the IXP in competition with members
 - (There is nothing wrong with charging different flat fees for 1Gbps, 10Gbps, 100Gbps etc ports as they all have different hardware costs on large chassis switches)

What can go wrong?

Competition

- Too many exchange points in one locale
 - Competing exchanges defeats the purpose
- Becomes expensive for ISPs to connect to all of them
 - So they don't, or won't, and local traffic suffers, defeating the viability of the IXPs
- An IXP:
 - is **NOT** a competition
 - is **NOT** a profit-making business

What can go wrong?

Rules and Restrictions

- IXP tries to compete with their membership
 - Offering services that ISPs would/do offer their customers
 - **In reality, IXPs are operated by the members for the members**

- IXP is run as a closed privileged club e.g.:
 - Restrictive membership criteria
 - **In reality, a participant needs to have an ASN, their own independent address space, and their own transit arrangements**

- IXP located in a data centre with restricted physical/transmission access
 - **IXP must be a neutral interconnect in a neutral location**

What can go wrong?

Rules and Restrictions

- IXP charges for traffic
 - So do transit providers – **charging for traffic is a sure way of ending the viability of the IXP**
- IXPs providing access to end users rather than just Network Operators & Service Providers
 - **A participant at an IXP needs to have their own address space, their own ASN, and their own transit arrangements**
- IXPs interfering with member business decisions
 - **The most common error: Mandatory Multi-Lateral Peering**

What can go wrong?

Technical Design Errors

❑ Interconnected IXPs

- IXP in one location believes it should connect directly to the IXP in another location
- Who pays for the interconnect?
- How is traffic metered?
- Competes with the Network Operators who already provide transit between the two locations
 - ❑ Who then refuse to join IX, harming the viability of the IX
- Metro interconnections for IXPs is fine!
 - ❑ Many examples of large IXPs with several sites distributed over the metro area (LINX, AMS-IX, DE-CIX, Netnod,...)

What can go wrong?

Technical Design Errors

- Members bridge the IXP LAN back to their offices
 - “We are poor, we can’t afford a router”
 - Financial benefits of connecting to an IXP far outweigh the cost of a router
 - In reality it allows the members to connect any devices to the IXP LAN — with disastrous consequences for the security, integrity and reliability of the IXP

What can go wrong?

Routing Design Errors

- Route Server peering mandated
 - Mandatory peering has no history of success
 - ISPs have no incentive to learn BGP
 - Therefore have no incentive to understand peering relationships, peering policies, &c
 - Entirely dependent on operator of RS for troubleshooting, configuration, reliability
 - The RS can't be run by committee!
- Route Server is designed to assist with scaling peering at IXPs

What can go wrong?

Routing Design Errors (cont)

- ❑ iBGP Route Reflector used to distribute prefixes between IXP participants
- ❑ Claimed advantages:
 - Participants don't need to know about or run BGP
 - Allows an IXP to be started very quickly
 - IXP operator has full control over member activities
 - ISP participants routers sit inside IXP's ASN
- ❑ All are disadvantages!
 - Participants never learn BGP
 - Participants have no policy control, IXP policies could impact the participants networks
 - IXP is an ethernet switch, not an Internet operator
 - IXP operator is single point of failure
 - Migration to true IXP with RS is very difficult

What can go wrong: Summary

- ❑ Not a transit business, just an L2 switch
- ❑ If charging, fair cost recovery only
- ❑ Not a competitive service
- ❑ No oppressive rules & restrictions
- ❑ No Mandatory Peering
- ❑ No bureaucratic management
- ❑ No interconnection with other IXPs
- ❑ No bridging of IX LAN back to members
- ❑ No Route Reflector, use a Route Server to scale

More Information

Exchange Point Policies & Politics

- AUPs
 - Acceptable Use Policy
 - Minimal rules for connection
- Fees?
 - Some IXPs charge no fee
 - Other IXPs charge cost recovery
 - A few IXPs are commercial
- Nobody is obliged to peer
 - Agreements left to individual members, not mandated by IXP

Exchange Point etiquette

- ❑ Don't point default route at another IXP participant
- ❑ Be aware of third-party next-hop
- ❑ Only announce your aggregate routes
 - Read RIPE-399 and RIPE-532 first
 - www.ripe.net/ripe/docs/ripe-399
 - www.ripe.net/ripe/docs/ripe-532
- ❑ Filter! Filter! Filter!

Exchange Point Examples

- Hundreds of Internet Exchange Points globally
- Those using IXP Manager are on this map:
 - <https://www.ixpmanager.org/community/world-map>

Features of IXPs (1)

- Redundancy & Reliability
 - Multiple switches, UPS/Generator
- Support
 - NOC to provide 24x7 support for problems at the exchange
- DNS, Route Collector/Server, Content Caches & NTP servers
 - ccTLD & root servers
 - Content caches
 - Content redistribution systems
 - Route Collector – Routing Table view

Features of IXPs (2)

- Location
 - Neutral, secure & accessible co-location facilities
- Address space
 - Public address for Peering LAN
 - Public address for IXP Services LAN
- AS Number
 - Private ASN needed for Route Collector (if deployed)
 - Public ASN needed for Route Server
 - Public ASN needed for IXP Services
- Route servers
- Statistics
 - Traffic data – for membership

IXP Creation

- No economy or circumstance is unique or different
 - The first excuse for not creating an IXP is “we don’t need one”
 - The second excuse for not creating an IXP is “oh, it is different here”
- Every locality has its differences
 - But every locality wants to
 - Keep local traffic local
 - Improve network performance and QoS
 - Improve local Internet economy
 - The available technology is the same for every network operator everywhere
 - There is no excuse for not improving the local Internet

Eco System Development

- Create IXP association
 - Formed by members who have a port on the IXP
- IXP members meet regularly
 - IXP Board meetings
 - IXP Operational strategy and direction
- IXP Technical community could also meet too
 - Network operators meeting, involving network and systems operations technicians & engineers
 - Aligned with IXP Association/member meetings
 - Could lead to creation of a Network Operators Group
- IXP could facilitate the creation of a NOG
 - The same technicians & engineers are involved in both!

Local Internet Exchange Point

- ❑ Defined as a public peering point serving the local Internet industry
- ❑ Local means where it becomes cheaper to interconnect with other members at a common location than it is to pay transit to another network operator to reach the same consumer base
 - Local can mean different things in different regions!

Regional Internet Exchange Point

- These are also “local” Internet Exchange Points
- But also attract regional ISPs and ISPs from outside the locality
 - Regional ISPs peer with each other
 - And show up at several of these Regional IXPs
- Local ISPs peer with ISPs from outside the locality
 - They don’t compete in each other’s markets
 - Local ISPs don’t have to pay transit costs
 - ISPs from outside the locality don’t have to pay transit costs
 - Quite often ISPs of disparate sizes and influences will happily peer – to defray transit costs

Industry Associations

□ IX-F

- The Internet Exchange Federation
 - <http://www.ix-f.net/>
- The federation of Internet Exchange Associations

□ Euro-IX

- The European Internet Exchange Association
- Members from Europe, associate members from around the world
- Website has all the information needed to start an IXP
 - <https://www.euro-ix.net/starting-an-ixp>
- IXP Best Practice documentation:
 - <https://www.euro-ix.net/euro-ix-bcp>
- Peering Toolbox:
 - <https://peeringtoolbox.euro-ix.net/en/>

Industry Associations

□ APIX

- Asia Pacific Internet Exchange association
- Meets twice a year, during APRICOT and APNIC conferences
 - <http://apix.asia>

□ Af-IX

- The African IXP Association
- Meets along with the African Peering Forum
 - <http://www.af-ix.net/>

□ LAC-IX

- The Latin American & Caribbean IX Association
 - <http://www.lac-ix.org/>

More info about interconnects

□ Telegeography

- <http://www.telegeography.com/telecom-resources/internet-exchange-map/>
- A collection of ISP interconnect points
- **Beware!! Not all the Telegeography listings are IXPs!**

□ Packet Clearing House

- IXP Directory: <https://www.pch.net/ixp/dir>

□ Internet Society

- IXP Toolkit: <http://www.ixptoolkit.org/>

Summary

- ❑ IXP is a Layer 2 infrastructure
- ❑ At least three players required (two is okay too)
 - Meeting in an open and neutral location
- ❑ Minimal rules
- ❑ Minimal bureaucracy
- ❑ Cost recovery
- ❑ Encourage participation by all autonomous networks
- ❑ Develop the local Internet eco-system
